Question 7
Correct
Mark 1.00 out of 1.00
 In the code below assume that each function can be executed concurrently by many threads/processes.
 Ignore syntactical issues, and focus on the semantics.
 This program is an example of
 spinlock a, b; \ensuremath{//} assume initialized
 thread1() {
     spinlock(b);
     //some code;
     spinlock(a);
      //some code;
     spinunlock(b);
      spinunlock(a);
 thread2() {
      spinlock(a);
      //some code;
      spinlock(b);
      //some code;
      spinunlock(b);
      spinunlock(a);

   a. Deadlock

  O b. Self Deadlock
  O c. None of these
  \bigcirc d. Deadlock or livelock depending on actual race
  O e. Livelock
 Your answer is correct.
 The correct answer is: Deadlock

 Your answer is partially correct.
 You have correctly selected 2.
 The correct answer is: static inline uint
 xchg(volatile uint *addr, uint newval)
  uint result;
  // The + in "+m" denotes a read-modify-write operand.
  asm volatile("lock; xchgl %0, %1"
           "+m" (*addr), "=a" (result) :
           "1" (newval) :
          "cc");
  return result;
 \} \rightarrow Atomic compare and swap instruction (to be expanded inline into code), void
 sleep(void *chan, struct spinlock *lk)
  if(lk != &ptable.lock){
   acquire(&ptable.lock);
   release(lk);
  } → Avoid a self-deadlock, void
 acquire(struct spinlock *lk)
  __sync_synchronize(); → Tell compiler not to reorder memory access beyond this line

	is partially correct.
The correct a Redundancy Combining fi aligns all me Limits the siz location in G	answer is: Many copies of Superblock → Redundancy to ensure the most crucial data structure is not lost, Free blocks count in superblock and group descriptor → to help fsck restore consistency, Used directories count in group descriptor → attempt is made to evenly spread the first-level directories, this count is used there, le type and access rights in one variable → saves 1 byte of space, rec_len field in directory entry → allows holes and linking of entries in directory, File Name is padded → mory accesses on word boundary, improving performance, Inode bitmap is one block → limits total number of files that can belong to a group, Block bitmap is one block → te of a block group, thus improvising on purpose of a group, Mount count in superblock → to enforce file check after certain amount of mounts at boot time, Inode table roup Descriptor → Obvious, as it's per group and not per file-system, Inode table → All inodes are kept together so that one disk read leads to reading many inodes sectively doing a buffering of subsequent inode reads, and to save space on disk, A group → Try to keep all the data of a directory and it's file close together in a group
